zFacts on ethanol

See yellow **highlights** on the [following page\(s\)](#).

---

### Corrections to a study done at UC Berkeleys Renewable and Appropriate Energy Laboratory, and Published in *Science* magazine, Jan 2006.

- Fact:**
1. Imported energy inputs to ethanol production are 42% of ethanol's energy inputs.
  2. GHG reduction by corn ethanol is 7.4%
  3. GHG reduction by cellulosic ethanol is 88.3%

**Source:** Supporting Online Material for: Ethanol Can Contribute To Energy and Environmental Goals. Version 1.1, May 12, 2006. Article published in *Science* 27 January 2006: Vol. 311. no. 5760, pp. 506 - 508. [Original Science Article](#)

#### Notes:

Imported Energy Inputs:

The energy inputs for corn "Ethanol Today" are listed on p.24  
Petroleum = 0.04, Natural gas = 0.28, coal = 0.41, other = 0.04.

All additional use of petroleum and gas must counted as increasing imports just as all replacement of gasoline is counted as reducing imports (not reducing US production).

$$(\text{Petroleum} + \text{gas}) / (\text{total energy input}) = 0.32 / 0.77 = 42\%.$$

This is the percentage of input energy that increases imports.

GHG Reduction for corn ethanol:

From page 25.

The % GHG reduction from ethanol today =  $(94 - 87) / 94 = 7.4\%$ ,

GHG Reduction for cellulosic ethanol:

From page 25.

The % reduction from cellulosic ethanol =  $(94 - 11) / 94 = 88.3\%$

sensitivity analyses above) without being clear about how it was calculated or noting that it is based on obsolete data.

11. In Table 1, numerous reported values lack any citation or explanation, including embodied energy in: phosphorus, potassium, lime, herbicide and insecticide. Several of these values are 20-50% higher than values reported by other sources.
12. In Table 1, (4) is cited, but the values are from (43) (See note 20).
13. In Table 1, the entire column of Nitrogen Fertilizer Production values is incorrectly converted from the English-unit version of the paper to SI, using  $(x \text{ BTU/lb}) / (948.45 \text{ BTU/MJ}) / (2.205 \text{ lb/kg})$  to compute MJ/kg. The correct conversion multiplies, rather than divides, the last term, i.e.  $(x \text{ BTU/lb}) / (948.45 \text{ BTU/MJ}) * (2.205 \text{ lb/kg})$ . So, for example, the N energy value reported by the 2002 version of the paper, 18392 BTU/lb is converted to 8.80 MJ/kg when the correct value is 45.75 MJ/kg. However, it appears that totals were converted directly to SI as totals, rather than by adding up the incorrectly converted values. Thus, the reported final results are correct despite the intermediate error.

**Figure S3. Energy Inputs and GHG Emissions for Gasoline and Ethanol**

Alternative metrics for evaluating ethanol based on the intensity of primary energy inputs (MJ) per MJ of fuel and of net greenhouse gas emissions (kg CO<sub>2</sub>-equivalent) per MJ of fuel. For gasoline, both petroleum feedstock and petroleum energy inputs are included. "Other" includes nuclear and hydrological electricity generation. Relative to gasoline, ethanol produced today is much less petroleum-intensive but much more natural gas- and coal-intensive. Production of ethanol from lignite-fired biorefineries located farm from where the corn is grown results in ethanol with a high coal intensity and a moderate petroleum intensity. Cellulosic ethanol is expected to have an extremely low intensity for all fossil fuels and a very slightly negative coal intensity due to electricity sales that would displace coal.

**Table S3. EBAMM Results**

Data for six studies of corn ethanol and three cases using the EBAMM model and published data. Values for gasoline account for coproducts.

	Reference	EBAMM results for selected studies						EBAMM cases
